Winter 2021

Context: interactive decision making in unknown environment **Aim**: Design systems to amass reward in many environments.

Context: interactive decision making in unknown environment **Aim**: Design systems to amass reward in many environments.

Main distinction: model of environment

- Reinforcement Learning action affects future state
- Bandits action affects observation
- Full Inf. Online Learning action affects reward

Coming up:

- (1) Full Information Online Learning
- (2) Bandit Problems (or just "Bandits")
- (3) Regret analysis in RL

Full Information Online Learning

1. Two Basic Problems

- Online Convex Optimization; Online Gradient Descent
- The Experts Problem; Exponential Weights

2. Two Peeks Beyond the Basics

- Follow the Regularized Leader and Mirror Descent
- Online Quadratic Optimization; Online Newton Step
- 3. Conclusion and Extensions

- Focus on losses (negative rewards)
- Model Environment as Adversary
- Online Convex Optimization (OCO) abstraction.

OCO Problem

Protocol: Online Convex Optimization

Given: game length *T*, convex action space $\mathcal{U} \subseteq \mathbb{R}^d$

For t = 1, 2, ..., T,

- The learner picks action $oldsymbol{w}_t \in \mathcal{U}$
- The adversary picks convex loss $f_t : U \to \mathbb{R}$
- The learner observes $f_t \triangleleft$ full information
- The learner incurs loss $f_t(w_t)$

OCO Problem

Protocol: Online Convex Optimization

Given: game length *T*, convex action space $\mathcal{U} \subseteq \mathbb{R}^d$

For t = 1, 2, ..., T,

- The learner picks action $oldsymbol{w}_t \in \mathcal{U}$
- The adversary picks convex loss $f_t : \mathcal{U} \to \mathbb{R}$
- The learner observes $f_t \triangleleft$ full information
- The learner incurs loss $f_t(w_t)$

The goal: control the regret (w.r.t. the best point after *T* rounds)

$$\mathcal{R}_{\mathcal{T}} = \sum_{t=1}^{\mathcal{T}} f_t(oldsymbol{w}_t) - \min_{oldsymbol{u} \in \mathcal{U}} \sum_{t=1}^{\mathcal{T}} f_t(oldsymbol{u})$$

using a computationally efficient algorithm for learner.

・ロト ・回 ト ・ヨト ・ヨト

Design Principle

Learner needs to "chase" the best point arg min_{$u \in U$} $\sum_{t=1}^{T} f_t(w_t)$. But doing so naively overfits.

Idea: add regularization. Two manifestations:

- Penalization "FTRL style"
- Update iterates, but only slowly "MD style"

Will see examples of both. For our purposes, these are roughly equivalent

Online Gradient Descent (OGD) Algorithm

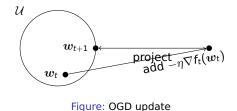

Let \mathcal{U} be a convex set containing 0. Fix a learning rate $\eta > 0$.

Algorithm: Online Gradient Descent (OGD)

OGD with learning rate $\eta > {\rm 0}$ plays

$$w_1 = 0$$
 and $w_{t+1} = \Pi_{\mathcal{U}} (w_t - \eta \nabla f_t(w_t))$

where $\Pi_{\mathcal{U}}(w) = \arg \min_{u \in \mathcal{U}} \|u - w\|$ is the projection onto \mathcal{U} .

Algorithm: OGD

$$w_1 = 0$$
 and $w_{t+1} = \Pi_{\mathcal{U}} (w_t - \eta \nabla f_t(w_t))$

Assumption: Boundedness

Bounded domain $\max_{u \in U} \|u\| \le D$ and gradients $\|\nabla f_t(w_t)\| \le G$.

Algorithm: OGD

$$oldsymbol{w}_1 = oldsymbol{0}$$
 and $oldsymbol{w}_{t+1} = oldsymbol{\Pi}_\mathcal{U} \left(oldsymbol{w}_t - \eta
abla f_t(oldsymbol{w}_t)
ight)$

Assumption: Boundedness

Bounded domain $\max_{u \in U} \|u\| \le D$ and gradients $\|\nabla f_t(w_t)\| \le G$.

Theorem (OGD regret bd, Zinkevich 2003)

$$\mathcal{R}_{\mathcal{T}} = \sum_{t=1}^{T} f_t(w_t) - \min_{u \in \mathcal{U}} \sum_{t=1}^{T} f_t(u) \leq \frac{1}{2\eta} D^2 + \frac{\eta}{2} T G^2$$

Algorithm: OGD

$$w_1 = 0$$
 and $w_{t+1} = \Pi_{\mathcal{U}} (w_t - \eta \nabla f_t(w_t))$

Assumption: Boundedness

Bounded domain $\max_{u \in U} \|u\| \le D$ and gradients $\|\nabla f_t(w_t)\| \le G$.

Theorem (OGD regret bd, Zinkevich 2003)

$$\mathcal{R}_{\mathcal{T}} = \sum_{t=1}^{T} f_t(w_t) - \min_{u \in \mathcal{U}} \sum_{t=1}^{T} f_t(u) \leq \frac{1}{2\eta} D^2 + \frac{\eta}{2} T G^2$$

Corollary

Tuning
$$\eta = rac{\mathsf{D}}{\mathsf{G}\sqrt{\mathsf{T}}}$$
 results in $\mathcal{R}_{\mathsf{T}} \leq \mathsf{D}\mathsf{G}\sqrt{\mathsf{T}}$.

Algorithm: OGD

$$w_1 = 0$$
 and $w_{t+1} = \Pi_{\mathcal{U}} (w_t - \eta \nabla f_t(w_t))$

Assumption: Boundedness

Bounded domain $\max_{u \in U} ||u|| \le D$ and gradients $||\nabla f_t(w_t)|| \le G$.

Theorem (OGD regret bd, Zinkevich 2003)

$$\mathcal{R}_{\mathcal{T}} = \sum_{t=1}^{T} f_t(w_t) - \min_{u \in \mathcal{U}} \sum_{t=1}^{T} f_t(u) \leq \frac{1}{2\eta} D^2 + \frac{\eta}{2} T G^2$$

Corollary

Tuning
$$\eta = rac{\mathsf{D}}{G\sqrt{\mathsf{T}}}$$
 results in $\mathcal{R}_{\mathsf{T}} \leq \mathsf{D}G\sqrt{\mathsf{T}}$.

Sublinear regret: learning overhead per round \rightarrow 0.

Ambuj Tewari (UMich)

Proof of OGD regret bound

Using convexity, we may analyse the tangent upper bound

$$f_t(w_t) - f_t(u) \leq \langle w_t - u,
abla f_t(w_t)
angle$$

Moreover,

$$egin{aligned} \|oldsymbol{w}_{t+1} - oldsymbol{u}\|^2 &= \| \Pi_{\mathcal{U}} \left(oldsymbol{w}_t - \eta
abla f_t(oldsymbol{w}_t)
ight) - oldsymbol{u}\|^2 \ &\leq \|oldsymbol{w}_t - \eta
abla f_t(oldsymbol{w}_t) - oldsymbol{u}\|^2 \ &= \|oldsymbol{w}_t - oldsymbol{u}\|^2 - 2\eta \langle oldsymbol{w}_t - oldsymbol{u},
abla f_t(oldsymbol{w}_t)
angle + \eta^2 \|
abla f_t(oldsymbol{w}_t)\|^2 \end{aligned}$$

Hence

$$\langle oldsymbol{w}_t - oldsymbol{u},
abla f_t(oldsymbol{w}_t)
angle \ \leq \ rac{\|oldsymbol{w}_t - oldsymbol{u}\|^2 - \|oldsymbol{w}_{t+1} - oldsymbol{u}\|^2}{2\eta} + rac{\eta}{2} \|
abla f_t(oldsymbol{w}_t)\|^2$$

Proof of OGD regret bound (ctd)

Summing over T rounds, we find

$$\begin{aligned} \mathcal{R}_{T}^{\boldsymbol{u}} &\leq \sum_{t=1}^{T} \langle \boldsymbol{w}_{t} - \boldsymbol{u}, \nabla f_{t}(\boldsymbol{w}_{t}) \rangle \\ &\leq \underbrace{\sum_{t=1}^{T} \frac{\|\boldsymbol{w}_{t} - \boldsymbol{u}\|^{2} - \|\boldsymbol{w}_{t+1} - \boldsymbol{u}\|^{2}}{2\eta}}_{\text{telescopes}} + \frac{\eta}{2} \sum_{t=1}^{T} \|\nabla f_{t}(\boldsymbol{w}_{t})\|^{2} \\ &\leq \frac{\|\boldsymbol{u}\|^{2} - \|\boldsymbol{w}_{T+1} - \boldsymbol{u}\|^{2}}{2\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \|\nabla f_{t}(\boldsymbol{w}_{t})\|^{2} \\ &\leq \frac{D^{2}}{2\eta} + \frac{\eta}{2} TG^{2} \end{aligned}$$

Is OGD regret bound of $\mathcal{R}_T \leq GD\sqrt{T}$ any good?

Is OGD regret bound of $\mathcal{R}_T \leq GD\sqrt{T}$ any good? Scaling with *G* and *D* is natural. What about \sqrt{T} ?

Is OGD regret bound of $\mathcal{R}_T \leq GD\sqrt{T}$ any good? Scaling with *G* and *D* is natural. What about \sqrt{T} ?

Theorem

Any OCO algorithm can be made to incur $\mathcal{R}_T = \Omega(\sqrt{T})$.

Image: A matrix

∃ >

Is OGD regret bound of $\mathcal{R}_T \leq GD\sqrt{T}$ any good? Scaling with G and D is natural. What about \sqrt{T} ?

Theorem

Any OCO algorithm can be made to incur $\mathcal{R}_T = \Omega(\sqrt{T})$.

Proof (by probabilistic argument).

Consider interval $\mathcal{U} = [-1, 1]$ and linear losses $f_t(u) = x_t \cdot u$ with i.i.d. Rademacher coefficients $x_t \in \{\pm 1\}$. Any algorithm has expected loss zero. The expected loss of the best action (± 1) is $-\mathbb{E}[|\sum_{t=1}^{T} x_t|] = -\Omega(\sqrt{T})$. Then as the expected regret is $\mathbb{E}[\mathcal{R}_T] = \Omega(\sqrt{T})$, there is a deterministic witness.

Here, the regret arises from overfitting of the best point.

OGD Discussion

- Adversarial result, super strong!
- Proof reveals it is really about linear losses.
- Matching lower bounds
- Successful in practise:
 - Practically all deep learning uses versions of online gradient descent (e.g. TensorFlow has AdaGrad [Duchi et al., 2011]) even though objective not convex.

• = •

From Learning Parameters to Picking Actions

We now turn to the second elementary online learning task.

- Decision Theoretic Online Learning
- Experts setting (also: Hedge setting)
- Prediction with Expert Advice

Protocol: Prediction With Expert Advice

Given: game length T, number K of experts

For t = 1, 2, ..., T,

- Learner chooses a distribution $w_t \in riangle_K$ on K "experts".
- Adversary reveals loss vector $\ell_t \in [0, 1]^{\kappa}$.
- Learner's loss is the **dot loss** $w_t^{\mathsf{T}} \ell_t = \sum_{k=1}^{K} w_t^k \ell_t^k$

- Learner's loss is the **dot loss** $w_t^{\mathsf{T}} \ell_t = \sum_{k=1}^{K} w_t^k \ell_t^k$

The goal: control the regret (w.r.t. the best expert after T rounds)

$$\mathcal{R}_{\mathcal{T}} = \sum_{t=1}^{\mathcal{T}} \boldsymbol{w}_t^{\mathsf{T}} \boldsymbol{\ell}_t - \min_{k \in [K]} \sum_{t=1}^{\mathcal{T}} \ell_t^k$$

using a computationally efficient algorithm for learner.

Let's apply what we know

Observations:

- Dot loss $u \mapsto u^{\intercal} \ell_t$ is *linear* (hence convex).
- Gradient $\ell_t \in [0, 1]^{\kappa}$ bounded by $\|\ell_t\| \leq \sqrt{\kappa}$.
- Probability simplex $\triangle_{\mathcal{K}}$ is contained in unit ball.

So: Instance of Online Convex Optimization. OGD with D = 1 and $G = \sqrt{K}$ gives $\mathcal{R}_T \le \sqrt{KT}$.

EW with *learning rate* $\eta > 0$ plays weights in round *t*:

$$w_t^k = \frac{e^{-\eta \sum_{s=1}^{t-1} \ell_s^k}}{\sum_{j=1}^{K} e^{-\eta \sum_{s=1}^{t-1} \ell_s^j}}.$$
 (EW)

or, equivalently, $w_1^k = \frac{1}{K}$ and

$$w_{t+1}^{k} = \frac{w_{t}^{k} e^{-\eta \ell_{t}^{k}}}{\sum_{j=1}^{K} w_{t}^{j} e^{-\eta \ell_{t}^{j}}}$$

(EW, incremental)

• E • .

Exponential Weigths / Hedge Algorithm

Algorithm: Exponential Weights (EW)

EW with *learning rate* $\eta > 0$ plays weights in round *t*:

$$w_t^k = \frac{e^{-\eta \sum_{s=1}^{t-1} \ell_s^k}}{\sum_{j=1}^{k} e^{-\eta \sum_{s=1}^{t-1} \ell_s^j}}.$$
 (EW)

or, equivalently, $w_1^k = \frac{1}{K}$ and

$$w_{t+1}^{k} = \frac{w_{t}^{k}e^{-\eta \ell_{t}^{k}}}{\sum_{j=1}^{K}w_{t}^{j}e^{-\eta \ell_{t}^{j}}}$$

(EW, incremental)

Theorem (EW regret bd, Freund and Schapire 1997)

The regret of EW is bounded by $\mathcal{R}_T \leq \frac{\ln K}{\eta} + T\frac{\eta}{8}$.

Corollary

Tuning
$$\eta = \sqrt{rac{8\ln K}{T}}$$
 yields $\mathcal{R}_T \leq \sqrt{T/2\ln K}.$

EW Analysis

Applying Hoeffding's Lemma to the loss of each round gives

$$\sum_{t=1}^{T} \boldsymbol{w}_{t}^{\mathsf{T}} \boldsymbol{\ell}_{t} \leq \sum_{t=1}^{T} \left(\underbrace{\frac{-1}{\eta} \ln \left(\sum_{k=1}^{K} \boldsymbol{w}_{t}^{k} \boldsymbol{e}^{-\eta \ell_{t}^{k}} \right)}_{\text{"mix loss"}} + \underbrace{\eta/8}_{\text{overhead}} \right)$$

Crucial observation is that cumulative mix loss telescopes

$$\sum_{t=1}^{T} \frac{-1}{\eta} \ln \left(\sum_{k=1}^{K} w_{t}^{k} e^{-\eta \ell_{t}^{k}} \right) = \sum_{t=1}^{T} \frac{-1}{\eta} \ln \left(\sum_{k=1}^{K} \frac{e^{-\eta \sum_{s=1}^{t-1} \ell_{s}^{k}}}{\sum_{j=1}^{K} e^{-\eta \sum_{s=1}^{t-1} \ell_{s}^{j}}} e^{-\eta \ell_{t}^{k}} \right)$$
$$= \sum_{t=1}^{T} \frac{-1}{\eta} \ln \left(\frac{\sum_{k=1}^{K} e^{-\eta \sum_{s=1}^{t-1} \ell_{s}^{j}}}{\sum_{j=1}^{K} e^{-\eta \sum_{s=1}^{t-1} \ell_{s}^{j}}} \right)$$
$$\stackrel{\text{telescopes}}{=} \frac{-1}{\eta} \ln \left(\sum_{k=1}^{K} e^{-\eta \sum_{s=1}^{T} \ell_{s}^{k}} \right) + \frac{\ln K}{\eta}$$
$$\leq \min_{k \in [K]} \sum_{t=1}^{T} \ell_{t}^{k} + \frac{\ln K}{\eta}.$$

Balancing act: "model complexity" vs "overfitting"

Theorem (OGD) $\mathcal{R}_T \leq \frac{D^2}{2\eta} + \frac{\eta}{2}G^2T$ Theorem (EW) $\mathcal{R}_T \leq \frac{\ln K}{\eta} + \frac{\eta}{8}T$

Balancing act: "model complexity" vs "overfitting"

```
Theorem (OGD)
\mathcal{R}_T \leq \frac{D^2}{2\eta} + \frac{\eta}{2}G^2T
```

Theorem (EW) $\mathcal{R}_T \leq \frac{\ln \kappa}{\eta} + \frac{\eta}{8}T$

Generates many follow-up questions:

- What if horizon T is not fixed? Anytime guarantees?
- What if gradient bound G is not known a priori?
- Can we have the actual gradient norms?
- What if model complexity (*D*) is not known? Not uniformly bounded? See Orabona and Cutkosky ICML'20 tutorial.

FTRL/MD "sneak peek"

Q: What if my domain does not look like either ball or simplex?

Algorithm: Follow the Regularized Leader (FTRL) (with linearized losses)

$$egin{aligned} egin{aligned} egin{aligne} egin{aligned} egin{aligned} egin{aligned} egin$$

Algorithm: Mirror Descent (MD)

$$m{w}_{t+1} = rgmin_{m{u}\in\mathcal{U}} \langlem{u},
abla f_t(m{w}_t)
angle + rac{1}{\eta} m{B}(m{u}\|m{w}_t)$$

 Regularizer R

 Examples:
 OGD
 sq. Euclidean norm

 EW
 Shannon entropy

Bregman Divergence *B* sq. Euclidean distance Kullback-Leibler divergence

Other entropies: Burg, Tsallis, Von Neumann, ... Connections to continuous exponential weights [van der Hoeven et al., 2018].

FTRL/MD "sneak peak" performance

Algorithm: Follow the Regularized Leader (FTRL) (with linearized losses)

$$w_{t+1} = \underset{u \in \mathcal{U}}{\operatorname{arg\,min}} \sum_{s=1}^{t} f_s(u) + \frac{1}{\eta} R(u)$$
$$w_{t+1} = \underset{u \in \mathcal{U}}{\operatorname{arg\,min}} \sum_{s=1}^{t} \langle u, \nabla f_s(w_s) \rangle + \frac{1}{\eta} R(u)$$

Algorithm: Mirror Descent

$$m{w}_{t+1} = rgmin_{m{u}\in\mathcal{U}} \langlem{u},
abla f_t(m{w}_t)
angle + rac{1}{\eta} m{B}(m{u}\|m{w}_t)$$

Theorem (AdaFTRL, Orabona and Pál 2015)

Fix a norm $\|\cdot\|$ with associated dual norm $\|\cdot\|_{\star}$. Let $R: \mathcal{U} \to [0, D^2]$ be strongly convex w.r.t. $\|\cdot\|$. AdaFTRL ensures

$$\mathcal{R}_T \leq 2D \sqrt{\sum_{t=1}^T \|\nabla f_t(w_t)\|_\star^2} + 2 \cdot \textit{loss range}.$$

Ambuj Tewari (UMich)

Quadratic Losses

So far we used convexity to "linearise"

$$f_t(\boldsymbol{u}) \geq f_t(\boldsymbol{w}_t) + \langle \boldsymbol{u} - \boldsymbol{w}_t,
abla f_t(\boldsymbol{w}_t)
angle,$$

and our methods essentially operated on linear losses. But what if we know there is curvature?

- How to represent/quantify curvature?
- How to efficiently manipulate curvature?
- How much can we reduce the regret?

Curvature assumptions

Assumption: Quadratic loss lower bound

There is a matrix $M_t \succeq 0$ such that

$$f_t(u) \ \geq \ \underbrace{f_t(w_t) + \langle u - w_t,
abla f_t(w_t)
angle + rac{1}{2}(u - w_t)^\intercal M_t(u - w_t)}_{=:q_t(u)}$$

for each $u \in U$.

イロト イヨト イヨト イヨ

Curvature assumptions

Assumption: Quadratic loss lower bound

There is a matrix $M_t \succeq 0$ such that

$$f_t(u) \ \geq \ \underbrace{f_t(w_t) + \langle u - w_t,
abla f_t(w_t)
angle + rac{1}{2}(u - w_t)^{\intercal}M_t(u - w_t)}_{=:q_t(u)}$$

for each $u \in U$.

Two main classes of instances

- squared Euclidean distance: $f_t(u) = \frac{1}{2} ||u x_t||^2$ satisfies the assumption with $M_t = I$. More generally, strongly convex functions have $M_t \propto I$.
- linear regression: $f_t(u) = (y_t \langle u, x_t \rangle)^2$ satisfies the assumption with $M_t = x_t x_t^{\mathsf{T}}$. More generally, exp-concave functions have $M_t \propto \nabla_t f_t(w_t) \nabla_t f_t(w_t)^{\mathsf{T}}$.

ONS Algorithm

Algorithm: Online Newton Step (FTRL variant)

$$w_{t+1} = \operatorname*{arg\,min}_{\boldsymbol{u}\in\mathcal{U}} \sum_{s=1}^t q_s(\boldsymbol{u}) + rac{1}{2} \|\boldsymbol{u}\|^2$$

Computing the iterate w_{t+1} amounts to minimising a convex quadratic. Often (depending on \mathcal{U}) closed-form solution or 1d line search.

- For $M_t \propto I$, takes O(d) per round.
- For rank-one M_t , can do update in $O(d^2)$ per round.
- In both cases, need to take care of projection onto $\ensuremath{\mathcal{U}}.$

ONS Performance

Algorithm: Online Newton Step (FTRL version)

$$oldsymbol{w}_{t+1} = \mathop{\mathrm{arg\,min}}\limits_{oldsymbol{u}\in\mathcal{U}} \sum_{s=1}^t q_s(oldsymbol{u}) + rac{1}{2} \|oldsymbol{u}\|^2$$

Theorem (ONS strcvx bd, Hazan et al. 2006)

For the strongly convex case $M_t \propto I$, ONS guarantees

 $\mathcal{R}_T = O(\ln T)$

Algorithm reduces to OGD with specific decreasing step-size η_t

Theorem (ONS expccv bd, Hazan et al. 2006)

For the exp-concave case $M_t \propto g_t g_t^{\intercal}$, ONS guarantees

$$\mathcal{R}_T = O(d \ln T)$$

- E - F

ONS Discussion

- Convex quadratics closed under taking sums. Run-time independent of T.
- Curvature gives huge reduction in regret: \sqrt{T} to $\ln T$.
- Matrix sketching techniques allow trading off run-time $O(d^2)$ vs O(d) with regret $O(\ln T)$ vs $O(\sqrt{T})$ [Luo et al., 2016].

.

Conclusion

- Online Learning a powerful and versatile tool
- Environment-as-black-box. Adversarial.
- Foundation for optimization, statistical learning, games, ...
- Techniques we saw here will reappear when we discuss adversarial bandits and adversarial MDPs

Conclusion

- Online Learning a powerful and versatile tool
- Environment-as-black-box. Adversarial.
- Foundation for optimization, statistical learning, games, ...
- Techniques we saw here will reappear when we discuss adversarial bandits and adversarial MDPs
- Some (of many) cool things we left out:
 - First-order (small loss) and second-order (small variance) bounds
 - Adaptivity to friendly stochastic environments (best of both worlds, interpolation)
 - Optimistic MD (predicting the upcoming gradient)
 - Non-stationarity (tracking, adaptive/dynamic regret, path length)
 - Beyond convexity (star-convex, geometrically convex, ...)
 - Supervised Learning and (stochastic) complexities (VC, Littlestone, Rademacher, ...)
